Optimizing a trajectory in a complex state space

Optimizing a trajectory in a complex state space

Optimizing a trajectory in a complex state space

Optimizing a trajectory in a complex state space

Key Points

- Trajectory numerical representation: accuracy and efficiency
 - geometric discretization
 - variational integrators
- Optimal control
 - discrete necessary conditions
 - local optimality
- Global solution among multiple homotopy classes
 - global state-space exploration

- optimal motion primitives
- dynamic programming

Framework for integration and control of vehicles

Preview of some results: examples of computed motions

Helicopter - optimal landingExample developed models:

Nonholonimic Integrators

- DLA: Discrete Lagrange-d'Alembert (Cortez, 2002)
- GNI: Geometric Nonholonomic Integrator (Ferraro, Iglesias, De Diego, 2007)

3

► *RDP*: Reduced d'Alembert-Pontryagin (Kobilarov, 2007)

A typical system setup

- ▶ configuration space $Q = M \times G$, configuration $q \in Q$
- ▶ *M* − *shape space*, e.g. joint angles
- G Lie group, e.g. SE(3) denoting the system pose
- nonholonomic constraints $\dot{q} \in \mathcal{D}$, distribution $\mathcal{D} \subset TQ$

< □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > <

- symmetries associated with group transformations
- external forces, e.g. gravity, friction

State Space Structure

Principle bundle $\pi: Q \to Q/G$; distribution $\mathcal{D}_q \subset T_q Q$, $q \in Q$.

$$\mathcal{V}_q = \mathcal{T}_q \operatorname{Orb}(q), \quad \mathcal{S}_q = \mathcal{D}_q \cap \mathcal{V}_q, \quad \mathcal{D}_q = \mathcal{S}_q \oplus \mathcal{H}_q.$$

- ▶ V_q: space of tangent vectors parallel to symmetry directions, i.e. the vertical space
- S_q : space of symmetry directions that satisfy the constraints (generated by $\mathfrak{s}_q = \{\xi \in \mathfrak{g} \mid \xi_Q(q) \in S_q\} \subset T_q Q/G$)
- ► H_q: space of tangent vectors that satisfy the constraints but are not aligned with any directions of symmetry, i.e. the *horizontal space*

Nonholonomic Connection

A principle connection $\mathcal{A}: TQ \to \mathfrak{g}$ with horizontal distribution \mathcal{H}_q .

Nonholonomic Connection (Bloch 2003; Cendra, Marsden, 2001)

Constructed as $\mathcal{A} = \mathcal{A}^{kin} + \mathcal{A}^{sym}$, \mathcal{A}^{kin} is the kinematic, \mathcal{A}^{sym} is the mechanical connection

$$g^{-1}\dot{g}+\mathcal{A}(r)\dot{r}=\Omega,$$

defining vertical and horizontal velocity components

$$\dot{q} = \operatorname{ver}_{r} \dot{q} + \operatorname{hor}_{r} \dot{q} \Leftrightarrow (\dot{r}, g^{-1} \dot{g})_{r} = (0, \Omega) + (\dot{r}, -\mathcal{A}(r)\dot{r})_{r}$$

where $\Omega \in \mathfrak{s}_r$ is the *locked angular velocity*. Vertical Variations $(\delta r, \delta g)$

Variations such that $\delta r = 0$ and $\delta gg^{-1} = \mathcal{A}(r,g) \cdot (\delta r, \delta g) \in \mathfrak{s}_r$

Horizontal Variations $(\delta r, \delta g)$

Variations such that $\mathcal{A}(r,g) \cdot (\delta r, \delta g) = 0$, or $(\delta r, g^{-1}\delta g) = (\delta r, -\mathcal{A}(r)\delta r) \in (TM \times \mathfrak{g})_r$

Discrete Trajectory

Pick coordinates $(r,g) \in M \times G$

Discrete Trajectory

Pick coordinates $(r,g) \in M \times G$

Discrete path $(r, u, p, g, \Omega, \mu)_d : \{t_k\}_{k=0}^N \to (TM \oplus T^*M) \times G \times \mathfrak{s} \times \mathfrak{g}^*$ subject to the constraints

$$r_{k+1} - r_k = hu_k, \qquad \tau^{-1}(g_k^{-1}g_{k+1}) = h\xi_k,$$

where $\xi_k = \Omega_k - \mathcal{A}(r_{k+\alpha})u_k$, with $r_{k+\alpha} := (1-\alpha)r_k + \alpha r_{k+1}$ for a chosen $\alpha \in [0, 1]$ and the map $\tau : \mathfrak{g} \to G$ represents the *difference* between two configurations in the group

三 つへの

Lagrange-D'Alembert-Pontryagin Nonholonomic Principle

Discrete Reduced LDAP Principle Denoting $\xi_k := \Omega_k - \mathcal{A}(r_{k+\alpha})u_k$:

$$\delta \sum_{k=0}^{N-1} h\left[\ell(r_{k+\alpha}, u_k, \xi_k) + \langle p_k, (r_{k+1} - r_k)/h - u_k \rangle \right]$$

$$+\langle \mu_k, \tau^{-1}(g_k^{-1}g_{k+1})/h - \xi_k \rangle \Big] + \sum_{k=0} \left[h\langle f_{k+\alpha}, \delta r_{k+\alpha} \rangle \right] = 0,$$

subject to:

vertical variations $(\delta r_k, g_k^{-1} \delta g_k) = (0, \eta_k), \eta_k \in \mathfrak{s}_{r_k}$ horizontal variations $(\delta r_k, g_k^{-1} \delta g_k) = (\delta r_k, -\mathcal{A}(r_k) \delta r_k),$

 $\ell(r,\dot{r},\xi) = L(r,\dot{r},e,g^{-1}\dot{g})$: the reduced Lagrangian

Discrete Equations of Motion

$$g_{k}^{-1}g_{k+1} = \tau(h(\Omega_{k} - \mathcal{A}(r_{k+\alpha})u_{k})),$$

$$r_{k+1} - r_{k} = hu_{k},$$

$$\mu_{k} = \frac{\partial \ell_{k+\alpha}}{\partial \Omega},$$

$$\langle \mathcal{DEP}_{\tau}(k), e_{b}(r_{k}) \rangle = 0,$$

$$\left(\frac{\partial \ell_{k+\alpha}}{\partial u} - \frac{\partial \ell_{k-1+\alpha}}{\partial u}\right) - h\left(\alpha \frac{\partial \ell_{k-1+\alpha}}{\partial r} + (1-\alpha) \frac{\partial \ell_{k+\alpha}}{\partial r}\right)$$

$$= \mathcal{A}(r_{k})^{*} \mathcal{DEP}_{\tau}(k) + h\left(\alpha f_{k-1+\alpha} + (1-\alpha) f_{k+\alpha}\right),$$

where the discrete Euler-Poincaré operator \mathcal{DEP}_{τ} is defined as

$$\mathcal{DEP}_{\tau}(k) := (\mathsf{d}\tau_{h(\Omega_k - \mathcal{A}(r_{k+\alpha})u_k)}^{-1})^* \mu_k - (\mathsf{d}\tau_{-h(\Omega_{k-1} - \mathcal{A}(r_{k-1+\alpha})u_{k-1})}^{-1})^* \mu_{k-1}$$

Disrete Euler-Poincare equations

• the unconstrained case Q = G

Figure: Tangent maps $d\tau^{-1}$ transforming momenta

 $\begin{array}{c|c} \mbox{Continuous} & \mbox{Discrete} \\ \hline \dot{\mu} = \mbox{ad}_{\xi}^{*} \mu + f & (\mbox{d}\tau_{h\xi_{k}}^{-1})^{*} \mu_{k} - (\mbox{d}\tau_{-h\xi_{k-1}}^{-1})^{*} \mu_{k-1} = hf_{k} \end{array}$

Implementation

Simple matrix operations. Example: G = SE(2), $\tau = cay$

$$\operatorname{cay}(\widehat{v}) = \begin{bmatrix} \frac{1}{4 + (v^{1})^{2}} \begin{bmatrix} (v^{1})^{2} - 4 & -4v^{1} & -2v^{1}v^{3} + 4v^{2} \\ 4v^{1} & (v^{1})^{2} - 4 & 2v^{1}v^{2} + 4v^{3} \\ 0 & 0 & 1 \end{bmatrix}$$

The maps $[d\tau_{\xi}^{-1}]$ can be expressed as the 3 \times 3 matrices:

$$[\mathsf{dcay}_{\widehat{v}}^{-1}] = \mathbf{I}_3 - \frac{1}{2}[\mathsf{ad}_v] + \frac{1}{4} \begin{bmatrix} v^1 \cdot v & \mathbf{0}_{3 \times 2} \end{bmatrix}$$

where

$$[\mathsf{ad}_v] = \left[egin{array}{ccc} 0 & 0 & 0 \ v^3 & 0 & -v^1 \ -v^2 & v^1 & 0 \end{array}
ight]$$

Note: a general method for any matrix group is also available

Discrete Nonholonomic Momentum Map

▶ Define the *local* discrete momentum map $\mathsf{J}^{\mathsf{loc}}$: $TM \times \mathfrak{g} \to \mathfrak{g}^*$

$$\mathsf{J}^{\mathsf{loc}}(\mathbf{r}_k, \mathbf{u}_k, \xi_k) = (\mathsf{d}\tau_{h\xi_k}^{-1})^* \mu_k, \quad \text{ where } \mu_k = \frac{\partial \ell}{\partial \xi} (\mathbf{r}_k + \alpha \mathbf{u}_k, \mathbf{u}_k, \xi_k),$$

and the spatial discrete momentum map $\mathsf{J}: \mathit{TQ} \to \mathfrak{g}^*$ through

$$\mathsf{J}(\mathbf{r}_k, u_k, \mathbf{g}_k, \mathbf{v}_k) := \mathsf{Ad}_{\mathbf{g}_k^{-1}}^* \mathsf{J}^{\mathsf{loc}}(\mathbf{r}_k, u_k, \mathbf{g}_k^{-1} \mathbf{v}_k),$$

< □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > <

where $(r_k, u_k) \in TM$ and $(g_k, v_k) \in TG$.

Discrete Nonholonomic Momentum Map

▶ Define the *local* discrete momentum map $\mathsf{J}^{\mathsf{loc}}$: $TM \times \mathfrak{g} \to \mathfrak{g}^*$

$$\mathsf{J}^{\mathsf{loc}}(\mathbf{r}_k, \mathbf{u}_k, \xi_k) = (\mathsf{d}\tau_{h\xi_k}^{-1})^* \mu_k, \quad \text{ where } \mu_k = \frac{\partial \ell}{\partial \xi} (\mathbf{r}_k + \alpha \mathbf{u}_k, \mathbf{u}_k, \xi_k),$$

~ ~

and the spatial discrete momentum map $\mathsf{J}: \mathit{TQ} \to \mathfrak{g}^*$ through

$$\mathsf{J}(r_k, u_k, g_k, v_k) := \mathsf{Ad}_{g_k^{-1}}^* \mathsf{J}^{\mathsf{loc}}(r_k, u_k, g_k^{-1} v_k),$$

where $(r_k, u_k) \in TM$ and $(g_k, v_k) \in TG$.

The momentum components J^{nh}_b(r_k, u_k, g_k, v_k) at point k along the basis elements e_b : Q → s are

$$\begin{aligned} \mathsf{J}_b^{\mathsf{nh}}(r_k, u_k, g_k, v_k) &= & \langle \mathsf{J}(r_k, u_k, g_k, v_k), e_b(r_k, g_k) \rangle \\ &= & \langle \mathsf{J}^{\mathsf{loc}}(r_k, u_k, g_k^{-1} v_k), e_b(r_k) \rangle. \end{aligned}$$

Discrete Momentum Map Evolution

Discrete Momentum Map Change

The momentum components J_b^{nh} evolve along discrete LDAP solution trajectories according to (denote $J(k) := J(r_k, u_k, g_k, v_k)$)

$$J_b^{hh}(k) - J_b^{hh}(k-1) = \langle J(k-1), e_b(r_k, g_k) - e_b(r_{k-1}, g_{k-1}) \rangle.$$

* consistent with previous results, e.g. Cortes, 2001; Ferraro et. al. 2007

Global Motion Planning

Global Exploration using Roadmaps Motion Primitives Dynamic Programming Search Extensions

Optimal Control

Goal: find an optimal trajectory to a desired state

- Compute the forces f(t) such that the systems moves from (q(0), q(0)) to (q(T), q(T)) during a time interval [0, T]
- minimizing the cost function

$$J(q,f) = \int_0^T C(q(t), f(t)) \mathrm{d}t, \qquad (1)$$

- e.g. minimum control effort: $C = \frac{1}{2} ||f||^2$; min. time: C = 1.
- subject to discrete equations of motion
- other constraints such as joint limits, obstacles, etc...

For clarity, consider the simpler case Q = G

Nonholonomic distribution $\mathfrak{h} \subset \mathfrak{g}$ (the *sub-Riemannian* case):

velocity
$$\xi \in \mathfrak{h} = \operatorname{span}\{X_1, ..., X_m\}, m < n, \quad \langle\!\langle X_i, X_j \rangle\!\rangle = \delta_{ij}$$

The dynamics satisfies

$$\begin{split} \langle (\mathrm{d}\tau_{h\xi_{k}}^{-1})^{*}\mu_{k} - (\mathrm{d}\tau_{-h\xi_{k-1}}^{-1})^{*}\mu_{k-1} - hf_{k}, X_{i} \rangle &= 0, \quad i = 1, ..., m, \\ \langle \langle \xi_{k}, X_{i} \rangle \rangle &= 0, \qquad \qquad i = m+1, ..., n, \\ \langle \mu_{k}, X_{i} \rangle &= \begin{cases} \langle \mathbb{I}\xi_{k}, X_{i} \rangle, & i = 1, ..., m \\ 0, & i = m+1, ..., n \end{cases}, \\ g_{k}^{-1}g_{k+1} &= \tau(h\xi_{k}). \end{split}$$

Necessary Conditions for Optimality

Define the Lagrangian multipliers $\eta_k \in \mathfrak{h}$, $\rho_k \in \mathfrak{h}^{\perp *}$, $\lambda_k \in \mathfrak{g}^*$ and and the *Hamiltonian* function

$$H_k := H(\xi_{k-1}, \xi_k, f_k, \eta_k) =$$

$$\langle (\mathsf{d}\tau_{h\xi_k}^{-1})^* \mathbb{I}\xi_k - (\mathsf{d}\tau_{-h\xi_{k-1}}^{-1})^* \mathbb{I}\xi_{k-1} - hf_k, \eta_k \rangle + \frac{h}{2} \|f_k\|^2$$

.

and the augmented discrete cost function

$$J'_{d}(\xi_{0:N-1}, f_{0:N}, \zeta_{0:N}, \rho_{0:N-1}, \lambda_{0:N-1}) \\ = \sum_{k=0}^{N} H_{k} + \sum_{k=0}^{N-1} \left(h \langle \rho_{k}, \xi_{k} \rangle + \langle \lambda_{k}, \tau^{-1}(g_{k}^{-1}g_{k+1}) - h\xi_{k} \rangle \right),$$

An optimal solution must satisfy

$$(\mathrm{d}\tau_{h\xi_{k}}^{-1})^{*}\lambda_{k} - (\mathrm{d}\tau_{-h\xi_{k-1}}^{-1})^{*}\lambda_{k-1} = 0,$$

where $\lambda_{k} = \frac{\partial(H_{k} + H_{k+1})}{\partial\xi_{k}} + \rho_{k} = \frac{\partial\widetilde{H}_{k}}{\partial\xi_{k}} + \rho_{k},$
 $\widetilde{H}_{k} := -\langle(\mathrm{d}\tau_{h\xi_{k}}^{-1})^{*}\mathbb{I}\xi_{k}, \mathrm{Ad}_{\tau(h\xi_{k})}\widetilde{f}_{k+1}^{\sharp} - \widetilde{f}_{k}^{\sharp}\rangle.$

Indirect Optimal Control Formulation

An optimal trajectory (minimizing the control effort $rac{h}{2}\sum_{k=0}^{N}\|\widetilde{f}_k\|^2$) satisfies

$$(\mathsf{d}\tau_{h\xi_k}^{-1})^*\lambda_k - (\mathsf{d}\tau_{-h\xi_{k-1}}^{-1})^*\lambda_{k-1} = 0, \quad k = 1, ..., N-1$$
(2)

$$\tau^{-1}(\tau(h\xi_0)\cdots\tau(h\xi_{N-1})\cdot(g(0)^{-1}g(T))^{-1})=0,$$
(3)

where $\lambda_k \in \mathfrak{g}^*$ is computed through

$$\begin{split} (\lambda_k)_i &= \left\langle \mathbb{I}(\mathsf{d}\tau_{h\xi_k}^{-1}(\nu_k)) - h(\mathsf{d}\tau_{h\xi_k})^* \operatorname{ad}_{\left(\mathsf{Ad}_{\tau(h\xi_k)}, \tilde{f}_{k+1}^{\sharp}\right)}^* (\mathsf{d}\tau_{h\xi_k}^{-1})^* \mathbb{I}(\xi_k) + \rho_k, e^i \right\rangle \\ &+ \left\langle \mathbb{I}(\xi_k), h\left(\mathsf{D}\,\mathsf{d}\tau_{h\xi_k}^{-1} \cdot e^i\right)(\nu_k) \right\rangle, \text{ where } \{e^i\} \text{ is the basis for } \mathfrak{g} \\ \nu_k &= \mathsf{Ad}_{\tau(h\xi_k)}, \tilde{f}_{k+1}^{\sharp} - \tilde{f}_k^{\sharp}, \\ \xi_k \in \mathfrak{h}, \ \rho_k \in \mathfrak{h}^{\perp *}. \end{split}$$

Nn equations (2)-(3) in the *Nn* unknowns $\xi_{0:N-1}$, $\rho_{0:N-1}$ solved with standard root-finding

- Benefits:
 - a principled way to construct mechanical integrators
 - respects the geometric structure of the state-space
 - numerical stability, accuracy
 - suitable for discrete optimal control

So far we have considered:

Optimal Control based on variational geometric integrators (approach termed DMOC: Discrete Mechanics and Optimal Control)

Benefits:

- a principled way to construct mechanical integrators
- respects the geometric structure of the state-space
- numerical stability, accuracy
- suitable for discrete optimal control
- Limitations (as with any optimal control method):
 - lots of complex constraint \Rightarrow expensive or even impossible
 - ▶ locally optimal \Rightarrow solution might be in a "bad" homotopy class

So far we have considered:

Optimal Control based on variational geometric integrators (approach termed DMOC: Discrete Mechanics and Optimal Control)

Benefits:

- a principled way to construct mechanical integrators
- respects the geometric structure of the state-space
- numerical stability, accuracy
- suitable for discrete optimal control
- Limitations (as with any optimal control method):
 - lots of complex constraint \Rightarrow expensive or even impossible
 - ▶ locally optimal \Rightarrow solution might be in a "bad" homotopy class
- ► Goal of this part:
 - extend DMOC to complex state-spaces cluttered with obstacles
 - find near globally optimal solution
 - guarantee efficiency

- DMOC primitives
 - simple optimized motions (precomputed)
 - invariant to group transformations
 - can be concatenated to produce complex trajectories
 - paths constructed from sequences of *compatible* primitives [1]
- Main benefits:
 - control problem decomposed into two simpler sub-problems:
 - 1. how to sequence primitives to create roadmap edges
 - 2. find optimal trajectory through dynamic programming

- DMOC primitives
 - simple optimized motions (precomputed)
 - invariant to group transformations
 - can be concatenated to produce complex trajectories
 - paths constructed from sequences of *compatible* primitives [1]
- Main benefits:
 - control problem decomposed into two simpler sub-problems:
 - 1. how to sequence primitives to create roadmap edges
 - 2. find optimal trajectory through dynamic programming
 - the complex differential control problem reduced to a lower dimensional algebraic one

Primitive Invariance

Denote state-space by X, state $x \in X$, and control set U, $u \in U$, e.g. X = TQ, x = (q, v)

• The flow $\varphi: X \times \mathbb{R} \to X$ of a primitive is *G*-invariant i.e.

 $\Phi_g(\varphi(x_0,t))=\varphi(\Phi_g(x_0),t),\quad \Phi_g \text{ is the group action with } g\in G$

• Two primitives π_1 and π_2 are *equivalent*, if $\exists g, T$ s.t.

$$(x_1(t), u_1(t)) = (\Phi_g(x_2(t-T)), u_2(t-T)), \forall t \in [t_{i,1}, t_{f,1}]$$

• Two primitives π_1 and π_2 are *compatible* if $\exists g_{12} \in G$ s.t.

$$x_1(T_1) = \Phi(g_{12}, x_2(0))$$

For discrete DMOC trajectories use discrete flow $\varphi_d: X \times \mathbb{N} \to X$

$$\varphi_d(x_k, i) \approx \varphi(x(kh), ih), \qquad x_k \approx x(kh)$$

Types of Primitives

Trim Primitives: continuously parametrized steady-state motions

$$\alpha: t \in [0, T] \rightarrow (x_{\alpha}(t), u_{a}(t))$$

along left invariant vector field $\xi_{\alpha} \in \mathfrak{g}$ with constant control inputs

$$x_{\alpha}(t) = \Phi(\exp(t\xi_{\alpha}), x_{\alpha}(0)), u_{\alpha}(t) = u_{\alpha}, \forall t \in [0, T].$$

The trim primitives are denoted

$$lpha(au): t \in [0, T]
ightarrow (\Phi(\exp(t\xi_{lpha}), x_{lpha}(0)), u_{lpha}),$$

where τ is called coasting time, and the set of all such primitives defined by $\mathcal{T}_{\alpha} = \{\alpha(\tau), \tau \geq 0\}.$

The displacement of a trim primitive α with coasting time τ is simply $g_{\alpha} = \exp(\tau \xi_{\alpha})$.

Maneuvers: switches b/n steady-state motions. Therefore they are defined to be compatible form left and right with trim primitives. The set of maneuvers is denoted M(S, G) ⊆ P(S, G). Formally, a maneuver π satisfies

$$\pi \in \mathcal{M}(\mathcal{S}, \mathcal{G}) \Leftrightarrow \exists \alpha, \beta \in \mathcal{T}(\mathcal{S}, \mathcal{G}) : \alpha \pi \beta \in \mathcal{P}(\mathcal{S}, \mathcal{G}).$$

The displacement as a result of executing the maneuver is denoted g_{π} .

Example: helicopter

Model – underactuated rigid body

- State: orientatation R ∈ SO(3), position x ∈ ℝ³, angular velocity ω ∈ ℝ³, linear velocity v ∈ ℝ³
- Controls: collective u_c, yaw u_ψ, rotor forward pitch γ_p, rotor sideways roll γ_r with control input covectors

$$f^{1}(\gamma) = (d_{t} \sin \gamma_{r}, d_{t} \sin \gamma_{p} \cos \gamma_{r}, 0, \sin \gamma_{p}, \cos \gamma_{p} \cos \gamma_{r}),$$

$$f^{2}(\gamma) = (0, 0, d_{r}, 0, -1, 0).$$

gravity; bounds on velocity and controls

▶ Primitives: invariant under $G' = SO(2) \times \mathbb{R}^3$

trim vector $\xi_{\alpha} \in \mathfrak{se}(3)$: invariance conditions $(\dot{\xi} = 0)$, with θ -pitch, ϕ -roll:

$$\xi_{\alpha} = \begin{bmatrix} 0 & -\omega_{z} & 0 & v_{x} \\ \omega_{z} & 0 & 0 & v_{y} \\ 0 & 0 & 0 & v_{z} \\ 0 & 0 & 0 & 0 \end{bmatrix}.$$

$$\gamma_{\rho} = 0, \gamma_{r} = 0, u_{\psi} = 0,$$

$$v_{y}\omega_{z} = -g\sin\theta,$$

$$-v_{x}\omega_{z} = g\cos\theta\sin\phi,$$

$$u_{c} = g\cos\theta\cos\phi$$

Example: helicopter (cont.)

State space exploration

- State space approximation/discretization: sets of orbit of invariant vector fields $X \approx \{x_{\alpha}(t) \mid \Phi_{g}(\varphi(x_{\alpha}, t)) = \varphi(\Phi_{g}(x_{\alpha}), t)\}$
- Each graph node is a set of orbits attached at some $g \in G$.
- ▶ The Control Problem: Find $\{\pi_i, \alpha_i, \tau_i\}$ such that

$$g_0^{-1}g_f = [\prod_i \exp(\tau_i \xi_{\alpha_i})g_{\pi_i}] \exp(\tau_N \xi_{\alpha_N})\}$$
